Data dictionary · jopacc_dataset.xlsx

What each column means — to the business, and to the pipeline

Covers the two sheets in the combined dataset: `Dataset` (12,537 rows, one row per extracted figure) and `Coverage` (one row per source report). Every value quoted below was checked against the file itself, not assumed.

Dataset sheet

`report_type` text, required

Business meaning: Which JoPACC publication this figure came from — `monthly`, `quarterly`, or `yearly`. Determines how far back the comparison in the source report reaches (a monthly report compares to last month; quarterly to last quarter; yearly to the prior year).

In the data: 8,832 rows monthly, 2,674 quarterly, 1,031 yearly. Read from the PDF's own page geometry (canvas size), not the filename.

`reporting_period` text, required

Business meaning: The period the *source report* covers — e.g. the August 2026 monthly report, regardless of which specific month a chart inside it happens to be showing. This is the report's identity, not necessarily the period a given row's value describes (see `period` below for that).

In the data: `2026-08` (monthly), `2025-Q2` (quarterly), `2026` (yearly).

`system` text

Business meaning: The payment system or clearing service the figure belongs to. JoPACC covers five: `cliq` (instant transfers), `jomopay` (mobile wallet switch), `efawateercom` (bill payment), `ach` (automated clearing house), `eccu` (electronic cheque clearing). Two non-system values also appear: `interoperability` (CliQ and JoMoPay figures shown together) and `summary` (a report's front overview page, where the source page names no specific system).

In the data: monthly reports carry all seven values above; quarterly and yearly reports carry the single value `unsectioned` instead — those two report types aren't split into system chapters the way monthly decks are, so system has to be read from the `metric` text itself on those rows.

`system_title` text

Business meaning: The literal chapter heading the source PDF used for this system, kept

verbatim so you can check it against the report.

In the data: Empty for quarterly/yearly rows, since those reports have no chapter dividers to read a heading from.

`metric` text

Business meaning: What is actually being measured — the closest thing to a column name in a conventional dataset. `Number of Transactions`, `Value of Transactions`, `Number of Users`. Also where a comparison callout lands: 123 rows carry a metric like `Decrease in the number` paired with the % it describes — these are JoPACC's own MoM/QoQ/YoY callouts, not something added on top.

In the data: free text, not a fixed list — deliberately, since forcing report wording into a fixed vocabulary would hide genuine differences in how a metric is named between reports.

`dimension` text

Business meaning: What the metric is broken out *by*, when it's broken out by anything — a category like `Jordanian`, `Money Transfer`, `On Us`. A flat headline KPI with no breakdown (total transactions for the month, say) legitimately has an empty dimension: there's nothing to split it by.

In the data: empty is common and not a defect — check `metric` before assuming a blank dimension means missing data.

`dimension_period` text

Business meaning: When the dimension itself is a time period — a chart's x-axis label — this is that period, normalised to a sortable form. A monthly trend chart with bars for Jun/Jul/Aug produces three rows whose `dimension` reads "Jun-26" etc. and whose `dimension_period` reads `2026-06`.

In the data: normalised examples include `2024-12`, `2025-Q2`, `2026` — same three period grains as `report_type`, because a chart can show a finer-grained trend than its own report type (a quarterly report's poster shows monthly bars inside a quarter, for instance).

`period` text, required

Business meaning: The period this specific row's value actually describes. This is the column to group or pivot on for a time series — **use this, not `reporting_period`,** for trend analysis. It resolves to `dimension_period` when the row came off a chart axis, and falls back to the report's own `reporting_period` otherwise (a flat KPI card has no axis of its own, so it describes the period the whole report covers).

`value` number

Business meaning: The figure itself, normalised to a plain number in base units — a printed "16.64B" becomes `16640000000`, so it sums, sorts, and charts correctly without any further cleanup.

In the data: the unit that number is in lives in the next column — **never compare two values without checking `unit` matches first** (mixing a JOD figure with a count is the single easiest mistake to make with this column).

`unit` text, required

Business meaning: What kind of number `value` is.

In the data: exactly three values appear — `count` (7,663 rows: transactions, users, billers — anything counted), `percent` (3,732 rows: shares and period-over-period changes, stored as the number as printed, e.g. 81.3, not as a fraction), `JOD` (1,142 rows: Jordanian Dinar amounts).

`raw_value` text

Business meaning: The literal text as printed in the report — `16.64B JOD`, unmodified. Kept specifically so a number can be checked against the PDF at a glance, without recomputing anything.

In the data: the single fastest way to catch a scaling mistake — if `raw_value` says `1.74 M` and `value` doesn't read as 1,740,000, something's wrong with that row specifically.

`confidence` number, 0–100

Business meaning: How sure the extraction process was that it read this figure correctly. Not a data-quality judgment about JoPACC's reporting — purely "did the text recognition step read this cleanly."

In the data: ranges from 40.3 to 100 across the whole dataset. Native-text rows are effectively always 100 (nothing to be uncertain about — the PDF's own text layer was read directly). Below roughly 70 is worth a manual glance at the source page before relying on the figure for anything decision-grade.

`extraction_method` text

Business meaning: How the figure was read off the page — `native` means the PDF's own embedded text was read directly (essentially error-proof); `ocr` means the page had no text layer at all (every glyph was outlined to a shape on export) and the figure had to be read from a rendered image instead.

In the data: 6,406 native, 6,131 OCR — almost an even split. This tracks a real change in how JoPACC exports its decks: everything from September 2025 onward is native; September 2024 through August 2025 is OCR. It is not a quality signal about the report's content, only about how it was technically produced.

`flagged` true/false

Business meaning: A one-glance signal that this row needs a second look before you treat it as settled — either the character-recognition step produced more than one possible reading for the same figure and this is just the one that won, or the row carries an explicit note about something uncertain in how it was matched to its label.

In the data: 1,975 of 12,537 rows (about 16%) are flagged. That is not 16% of the dataset being wrong — it's 16% worth spending thirty extra seconds on if the figure matters to a conclusion.

`source_pdf` text, required

Business meaning: The exact filename of the JoPACC report this row came from, as published. The audit trail back to the original document.

source_page `integer`

Business meaning: The page inside `source_pdf` this figure sits on. Combined with `source_pdf`, this is enough to find the exact spot in the exact PDF for any row in the dataset — the "cite report month and source for every figure" requirement is answerable directly from these two columns.

Coverage sheet

One row per source report, not per figure — a sanity-check summary, not analysis data. Useful for spotting a report that came back thin before you rely on it.

Column	Meaning
`report_type`	Same meaning as in the Dataset sheet.
`reporting_period`	Same meaning as in the Dataset sheet.
`rows`	How many Dataset rows this one report produced. A report with noticeably fewer rows than its neighbours of the same type is worth a look — it may mean a page failed to read rather than that the report genuinely had less to say.
`systems`	How many distinct `system` values appear for this report. Monthly reports should show 7; a monthly report showing fewer is a sign its section boundaries weren't all found correctly.
`metrics`	How many distinct metric names appear. Lower than its peers can mean genuinely less content, or it can mean OCR noise collapsed several real metric names into one generic fallback — check the flagged rate for that period before concluding it's the former.

Two things worth internalising before you use this

> **Group by `period`, not `reporting_period`, for any trend.** They agree for a flat headline KPI and disagree for anything read off a chart axis. Using the wrong one silently shifts every point in a trend chart by however far the axis reaches back.

> **An empty `system` value on a quarterly or yearly row is expected, not missing data.** Those two report types aren't chaptered by system the way monthly decks are — `unsectioned` is the correct value there, and the system the figure belongs to has to be read from `metric` instead.

Every count and example above was read directly from jopacc_dataset.xlsx, not estimated. Column behaviour was verified against the pipeline's own extraction logic where the two could disagree (confidence, extraction_method, period vs. reporting_period).
